Reactions between \([\alpha-PVMo_{10}O_{39}]^{8-}\), mono-lacunary Keggin monovanado-deca-molybdophosphate and transition metal cations Mn\(^{2+}\), Fe\(^{3+}\), Ca\(^{2+}\), N\(_{2}\)\(^{+}\) and Cr\(^{3+}\) in aqueous solution results in the formation of new polyoxometalate complexes, with the stoichiometry metal : ligand by 1:1. New complexes were isolated as potassium salts, i.e. \(K\left[\text{M}^{n+}(H\_2O)\text{PVMo}_{10}O_{39}\right] \cdot xH\_2O\). The molecular formula of complexes was determined by elemental and thermo-gravimetric analysis, UV-Vis, FT-IR, Raman, EPR spectroscopy and X-ray diffraction. The investigation results strongly suggest a Keggin-type structure with mixed addenda of new complexes in which the transition metal cations are coordinated by five oxygen atoms of the cavity of lacunary polyoxometalate anions and sixth oxygen atom originates in the water molecule in distorted Oh symmetry. Some of new complexes, \(K\left[Ni(H\_2O)\text{PVMo}_{10}O_{39}\right] \cdot xH\_2O (x = 16, 21)\) and \(K\left[\text{Cu}(H\_2O)\text{PVMo}_{10}O_{39}\right] \cdot 17H\_2O\), crystallized in monoclinic system, space group \(P2_1/c\). The electrocatalytic activity of the \(K\left[\text{Cu}(H\_2O)\text{PVMo}_{10}O_{39}\right] \cdot 17H\_2O\) compound towards \(H\_2O\_2\) was evidenced.

Keywords: Keggin polyoxometalates, FTIR, Raman, EPR spectroscopy, Cyclic voltammetry

Polyoxometalates (POMs) are metal-oxygen clusters that exhibit a fascinating variety of structures and properties, including size, shape, charge, density, acidity, redox states, stability, solubility, etc. Transition metal substituted polyoxometalates (TMSPs) have attracted a continually growing interest in the field of polyoxometalates chemistry, being of great interest in catalysis, material science and medicine [1-5]. The last thirty years have witnessed a large amount of work in order to prepare and characterize substituted Keggin polyoxotungstate species [6].

A widespread means of functionalizing polyoxometalates [1, 2] is the substitution of some of the addenda atoms with other elements. Substituting (Mo, W) with lower-valence atoms (V, Nb, Ta) has been deemed as interesting, as it leads to further oligomerization of polyoxometalates into larger structures [3, 7, 8], or coordination with electrophilic moieties [9, 10]. Keggin [11] type anions are the most widely studied polyoxometalates, structural information on those substituted with lower-valence atoms are well established [12-14].

Monolacunary \([\text{PVMo}_{10}O_{39}]^{8-}\), monovanado-decamolybdophosphate Keggin polyoxo-anion with mixed addenda, forms new complexes with transition metal cations, in which the metal-to-ligand ratio is 1:1. The aim of the present paper is to report the synthesis and investigation of five new complexes of the \([\text{PVMo}_{10}O_{39}]^{8-}\) ligand, with \(M^{n+}\) transition metal cations (Mn\(^{2+}\), Fe\(^{3+}\), Ca\(^{2+}\), N\(_{2}\)\(^{+}\) and Cu\(^{2+}\)) with a Keggin structure and 1:1 molar ratio, which correspond to the general formula \(K\left[M^{n+}(H\_2O)\text{PVMo}_{10}O_{39}\right] \cdot xH\_2O\). Complexes were investigated and characterized by FT-IR, UV-Vis, EPR spectroscopy, powder X-ray diffraction and electro-chemical measurements. This allowed the further determination of the behaviour of encapsulated transition metal ions, their coordination by Keggin fragments, the corresponding local symmetry and their structure.

Experimental part

All chemicals were obtained from commercial sources and used without further purification. Only distilled water was used in all procedures. Elemental analysis of P, Mo, V, Mn, Fe, Co, Ni and Cu was performed on a Varian ASA 220 type spectrophotometer. Potassium was determined by flamephotometry with an Eppendorf flame photometer. Thermal stability analyses were performed in air on a Paulik-Erdely OD-103 derivatograph (20-800°C) at 5°C min\(^{-1}\). FT-IR spectra were recorded in the 400-4000 cm\(^{-1}\) on a Biorad FTS 60A spectrophotometer using KBr pellets. Raman spectra were performed on solid powders at room temperature, using a DILOR OMARS 89 Raman spectrophotometer (\(\lambda_e = 1064\) nm). UV-VIS spectra were recorded in the 190-1100 nm on Shimadzu UV-VIS model mini-1240 spectrophotometer. EPR spectra were obtained with a Bruker ESP 380 spectrometer. X-ray diffraction (XRD) measurements were performed using a BRUKER D8 Advance X-ray diffractometer, working at 40 kV and 40 mA and the goniometer was equipped with a germanium monochromator in the incident beam. The X-ray diffraction patterns were collected in a step-scanning mode with steps of \(\Delta 2\theta = 0.01°\) using Cu K\(_{\alpha1}\) radiation (\(\lambda = 1.54056\) A) in the 2\(\theta\) range 5-80°. Corundum powder was used as standard for instrument broadening correction.

The cyclic voltammetry measurements were carried out using a computer-controlled electrochemical analyzer (PGStat 10, AutoLab, Nederlands). The conventional three electrodes cell was equipped with a graphite working electrode (3 mm diameter, Ringsdorf, Germany), a
platinum wire auxiliary electrode and an Ag/AgCl, KCl reference electrode, respectively. Before use, the working electrode was cleaned by polishing with successively finer grade emery paper and all electrochemical studies were performed at room temperature. The compounds solutions were freshly prepared just before use, by dissolving the appropriate amounts of complexes into the 0.25 M solution of Na₂SO₄, supporting electrolyte. The pH values of the solutions were adjusted using diluted H₂SO₄.

Synthesis of compounds

K₅[Fe(H₂O)PVMo₁₀O₃₉]·6H₂O (L): A solution containing 1.42 g (7.25 mmol) of NaVO₃·2H₂O solved in minimum quantity of distilled water was added dropwise with stirring to a mixture between 17.53 g (72.42 mmol) Na₂MoO₄·2H₂O and 1.00 g (7.25 mmol) NaH₂PO₄·H₂O dissolved in 50 mL distilled water. The resulting solution was stirred for 30 minutes at room temperature. When the solution cleared, the pH was adjusted at 4.7 with 1 M HCl solution. Any insoluble material was removed by filtration under suction and then dried in a desiccator. Yield: 6.85 g (43.6 %). UV (nm): 212, 310; IR (cm⁻¹): 3569 m, 3489 s, 3474 s, 3184, 1624 m, 1080 w, 1068 w, 1051 w, 945 s, 941 s, 872 m, 782 s, 593 m, 520 w; Raman (cm⁻¹): 1095 w, 987 s, 885 w, 779 s, 593 w, 523 w; Anal. Calcd (Found): K, 9.94 (9.89); Mo, 40.77 (40.89); V, 2.37 (2.37); Cu, 2.78 (2.78); P, 1.36 (1.36); H₂O, 14.19 (14.19) %.

K₅[Fe(H₂O)PVMo₁₀O₃₉]·8H₂O (2): The synthetic procedure above was followed using 0.37 g (2.30 mmol) FeCl₃ instead of MnCl₂·4H₂O. The addition of KCl (2 g) to the solution led to red-orange crystals of K₅[Fe(H₂O)PVMo₁₀O₃₉]·8H₂O, which were filtered off and dried in desiccator. Yield: 2.61 g (51 %). UV (nm): 212, 315; IR (cm⁻¹): 3470 sh, 3373 m, 1617, 1080 w, 1068 w, 1051 w, 942 s, 887 m, 779 s, 520 w; Raman (cm⁻¹): 989 s, 974 s, 229 m; Anal. Calcd (Found): K, 10.25 (10.08); Mo, 42.05 (42.18); V, 2.23 (2.15); Co, 2.58 (2.46); P, 1.36 (1.33); H₂O, 14.19 (14.19) %.

K₆[Mn(H₂O)PVMo₁₀O₃₉]·10H₂O (1): To a solution obtained by dissolving 5 g (2.30 mmol) K₅[Fe(H₂O)PVMo₁₀O₃₉]·6H₂O in 40 mL distilled water having pH = 4.3 by adding 1N HCl, a solution obtained by dissolving of 0.46 g (2.30 mmol) of MnCl₂·4H₂O, 2 g (26.8 mmol) of KCl power, and 1.00 g (7.25 mmol) of NaH₂PO₄·H₂O dissolved in 50 mL distilled water was added drop-wise under stirring. The pH was adjusted between 3.75-4.00 with 0.1 M HCl and 5% solution of KHCO₃ respectively. The mixture was kept at room temperature, 30 min under stirring. Any insoluble material was removed by filtration under suction and then to the filtrate was added 2 g (26.8 mmol) of KCl, and 2-3 days at 60°C. After 3 days the red-orange crystals of K₆[Mn(H₂O)PVMo₁₀O₃₉]·10H₂O were filtered off and washed with ethanol. The crystals were kept two days at room temperature in a desiccator. The complex was recrystallized from deionized water with ethanol and then dried in a desiccator. Yield: 2.65 g (43.6 %). UV (nm): 214, 314; IR (cm⁻¹): 3569 sh, 3470 sh, 3373 m, 1617 m, 1080 w, 1068 w, 1051 w, 945 sh, 932 s, 870 m, 782 m, 720 m, 680 m, 643 m, 522 m, 989 m, 945 sh, 939 vs, 874 s, 788 vs, 645 w, 518 w, 225 w; Raman (cm⁻¹): 995 s, 979 vs, 519 w, 235 m; Anal. Calcd (Found): K, 9.94 (9.89); Mo, 40.77 (40.89); V, 2.17 (2.02); Ni, 2.49 (2.41); P, 1.32 (1.28); H₂O, 16.82 (16.72) %.

K₆[Co(H₂O)PVMo₁₀O₃₉]·17H₂O (5): The synthetic procedure above was followed using 0.39 g (2.30 mmol) CuCl₂·6H₂O instead of MnCl₂·4H₂O. The addition of KCl (2 g) to the solution led to red-orange crystals of polyoxometalate complex, which were filtered off and dried in a desiccator. Yield: 2.0 g (38 %). UV (nm): 211, 316; IR (cm⁻¹): 3569 sh, 3470 sh, 3373 m, 1617 m, 1080 w, 1062 w, 1045 w, 941 s, 872 m, 782 s, 593 m, 520 w; Raman (cm⁻¹): 996 sh, 979 vs, 519 w, 235 m, 156 w, 108 w; Anal. Calcd (Found): K, 10.23 (10.20); Mo, 41.87 (41.95); V, 2.15 (2.12); Cu, 2.78 (2.62); P, 1.36 (1.33); H₂O, 14.16 (14.13) %.

Results and discussions

The thermal stability of 1-5 complexes was investigated by TG-DTG-DTA. The weight loss between 20-175°C corresponds to lattice water molecules content. The dehydration process is accompanied by two endothermic processes at ~70 and ~180°C as observed on the DTA curve. The second weight loss observed on the DTG curve between 270-350°C is assigned to the loss of the coordination molecule. According to the literature, the first exothermic peak of the synthetic procedure appeared between 30-30°C after the temperature of polyoxometalate decomposing [15], is regarded as the thermal stability sign of polyoxometalates [16]. For the compounds 1-5, the first exothermic peak appeared between 300-360°C, indicating a good thermal stability of the complexes in following order:

L (276°C) < 5 (331°C) < 1 (345°C) < 2 (346.5°C) < 3 (348.5°C) < 4 (351°C)

The endothermic processes at ~430°C and ~540°C are due to oxides mixture formation and structural transformations.

FT-IR spectra of 1-5 complexes in the range of 4000-400 cm⁻¹ are shown in figure 1 along with those of the monocarulacary Keggin ligand L. Comparing FT-IR frequencies of the monocarulacary ligand L with those 1-5 complexes of the transition metal cations, we have obtained information concerning the coordination of the transition cations in the vacant position of the monocarulacary polyoxometalate ligand. The similarity
between FT-IR spectra for L ligand and for 1-5 complexes shows that the main vibration bands are due to the polyoxometalate structure [17]. In the FT-IR spectrum of L ligand, the intense broad band at ~3374 cm⁻¹ is attributed to hydrogen-bonded ν as(OH) vibration, and in-plane δ(OH) bending appears as a medium band at 1624 cm⁻¹. The shoulders on the very broad ν as(OH) vibration band (3000-5570 cm⁻¹ region) are due to the coexistence of the crystallization and coordinated water molecules.

In spectra of 1-5 complexes, the intense broad vibration band, ν as(OH), between 3570-3370 cm⁻¹, corresponds to water involved in hydrogen bonds and is due to the crystallization water, as well. The in-plane OH bending δ(OH) appears in complexes 1-5 as a medium band between 1609-1617 cm⁻¹ involved in hydrogen bonds with neighbouring water molecules [17]. The ν as(P-Oi), where O is the internal oxygen atom which links P and mixed addenda of Mo and V, respectively, frequency appearing in the ligand L spectrum as two weak bands at 1042 cm⁻¹ and 1031 cm⁻¹, while in complexes 1-5 spectra these appearing as three weak bands, showing the presence of phosphorus as heteroatom in the polyoxometalate framework. The tiny shift of the ν as(P-Oi) anti-symmetric stretching vibrations towards higher energies in complexes 1-5 indicates that the coordination increases the cohesion of the monolacunary ligand structure around transition metal cations. Bands of stretching vibrations ν as(Mo-O t) and ν as(V-O t) in the ligand shown at 984 cm⁻¹ and 945 cm⁻¹, respectively, are superposed in spectra of the complexes 1-5, and shown as broad band between 932-944 cm⁻¹ [18]. The relative small shift of the ν as(V-O t) stretching vibrations, either towards lower frequencies is due to the fact that the terminal O t atoms are not involved in the coordination of the transition metal cations. The two bands at 929 (vs, sp) cm⁻¹ and 839 (m) cm⁻¹, respectively, for three centers Mo-O t-Mo bonds of the corner-sharing MoO 6 octahedron, are shown in the spectrum of the ligand and only one medium band appears in FT-IR spectra of the complexes (by 870 for 1, 858 for 2, 887 for 3, 874 for 4 and 872 for 5, cm⁻¹ respectively). The increase in the spectra of the complexes the ν as(Mo-O t-Mo) frequency for the three-center bonds of corner-sharing that belongs to the cap region indicates the shortening of these bonds after the metallic ions coordination. Similarly, two vibration bands for three-center Mo-O t-Mo bonds of the edge-sharing MoO 6 octahedron appear in the FT-IR spectra of the ligand at 807 (w) cm⁻¹ and 729 (m) cm⁻¹, respectively, suggesting that two non-equivalent bonding of this type is present. In complexes 1-5 one of them belonging to the belt region lost, but the other belonging to the cap region with the lower frequency remains (by 782 (vs) for 1, 776 (w) for 2, 779 (s) 3, 788 (s) for 4 and 782 (vs) for 5 cm⁻¹, respectively). The increase in the spectra of the complexes of the ν as(Mo-O c-Mo) frequencies for the three-center bonds of edge-sharing MoO 6 octahedron indicates the shortening of these bonds after the metallic ion coordination and increase the symmetry and stability of these compounds. In conclusions can be said that the shift of ν as(Mo-O c-Mo) and ν as(Mo-O t-Mo) frequencies for the bonds from the cap region of the monovacant Keggin units, shows the coordinate of each transition metallic ion by the oxygen atoms from corner-sharing and edge-sharing octahedron.

Raman spectra of 1-5 complexes in the 1200-100 cm⁻¹ are shown in figure 2 comparatively with those of the monolacunary Keggin ligand L. The Raman spectrum of the ligand shows the three characteristic bands at 960 (vs) cm⁻¹, 889 (m) cm⁻¹ and 229 (w) cm⁻¹, assigned to ν as(Mo-O t), ν as(Mo-O c) and ν as(Mo-O t), respectively. These bands are shifted in the Raman spectra of the complexes (at 987 (s), 885(sh) and 229 (w) cm⁻¹ for 1, 995 (s), 975 (sh) and 233 (w) cm⁻¹ for 2, 989 (s), 974 (s) and 229 (w) cm⁻¹ for 3, 991 (s), 975 (sh) and 235 (w) cm⁻¹ for 4, and 996 (sh), 979 (s) and 235 (m) cm⁻¹ for 5, respectively). In Raman spectra, the bands assigned to vibrations of the complexes 1-5, Mo-O t bonds were shifted towards higher energies, comparatively with the ligand. This suggests higher stability of the complexes [19, 20].

The electronic UV and Vis spectra were registered on aqueous solutions of the potassium salts of the complexes 1-5 and compared with those of the ligand or with the hexaaqua complexes of the Mn³⁺, Fe³⁺, Co²⁺, Ni²⁺ and Cu²⁺ in octahedral field [21]. UV spectra of polyoxometalate clusters generally exhibit two charge-transfer (CT) bands, characteristic to the polyoxoanionic framework, which are ascribed to oxygen-to-metal transitions. In UV spectrum of the ligand L, the broad ν CT band, due to d–p–d transitions from the three-center Mo-O t-Mo and Mo-O t-V bonds recorded at 321 nm/31150 cm⁻¹. The sharper ν CT Band, due to dπ-π transitions of the Mo=O t and V=O t bonds, have the maximum detected at 209 nm/47850 cm⁻¹. The UV
spectra of the ligand and complexes are also similar, proving that the charge transfer inside in polyoxometalate structure is not significantly affected by coordination. The lower energy band $\nu_1$ was shifted to higher frequencies in complexes spectra, compared to the ligand, and this is due to the increase of the symmetry, of the MoO$_6$ and VO$_6$ octahedron through coordination, which influences the electronic transfer from these bonds. The higher energy band $\nu_2$ was shifted to lower frequencies in complexes spectra, compared to the ligand, and this is due to the decrease of the symmetry, of the MoO$_6$ and VO$_6$ octahedron through coordination, which influences the electronic transfer from these bonds [22].

Visible spectra only show electron transfer bands of the Mn$^+$ transition metal ions coordinated by the ligand. However, the expected transition bands are not found in the spectrum of complex 1 and 2. The very low intensity d-d transitions of the (d$^5$) Fe$^{3+}$ and Mn$^{2+}$ ions, forbidden by the Laporte and spin selection rules, are totally masked by the $\nu_1$ charge transfer band, which extends from UV into the visible range [21]. This indicates that Fe$^{3+}$ and Mn$^{2+}$ ions are involved in the charge transfer in complexes 1 and 2.

The absorption bands of the 3-5 complexes recorded in the visible range were compared to those of the corresponding [Co(H$_2$O)$_6$]$^{2+}$, [Ni(H$_2$O)$_6$]$^{2+}$ and [Cu(H$_2$O)$_6$]$^{2+}$ aqua-cations in octahedral field conform to literature [21, 22]. The Vis spectrum of complex 3 (fig. 3A) shows the characteristic features of Co$^{3+}$ (d$^3$) ion in a distorted octahedral environment: show a band at 550 nm/18180 cm$^{-1}$ with a shoulder at 630 nm/15870 cm$^{-1}$ corresponding to the $^3A_g(F)\rightarrow^3T_{2g}(F)$ ($\nu_1$) and $^3A_g(F)\rightarrow^3T_{1g}(P)$ transitions.

The Vis spectrum of complex 4 (fig. 3B) shows the characteristic features of Ni$^{2+}$ (d$^8$) ion in a distorted octahedral environment: show two bands at 713 nm/14025 cm$^{-1}$ and 798 nm/12530 cm$^{-1}$ corresponding to the $^3A_g(F)\rightarrow^3T_{2g}(F)$ and $^3A_g(F)\rightarrow^3T_{1g}(P)$ transitions.

The visible spectrum of the complex 5 (fig. 3C) presents a broad absorption curve with a maximum at approximately 855 nm/11700 cm$^{-1}$ suggesting a distorted octahedral environment around the Cu$^{2+}$ (d$^9$) ion. This band can be attributed to the $^2E_g\rightarrow^2T_{2g}$ transition. Three transition are expected (d$_{xy}$ $\rightarrow$ d$_{z^2}$ and d$_{xy}$ $\rightarrow$ d$_{x^2}$), but these are very close in energy and give rise to a single asymmetric broad band. The greater shift in the case of the copper ion in the complex 5, as opposed to the aqua copper complex associated with the band symmetry can be traced back to the Jahn-Teller distortion.

In EPR spectra of the complexes 1, 3 and 4 the signals of the vanadium ions from ligand overlap the signals of the Mn$^{2+}$, Co$^{2+}$ and Ni$^{2+}$ ions. Although the signals of the vanadium ions are present in the spectrum of the compound 2 too, this spectrum can be interpreted.

EPR spectra of the compounds 2 and 5 were interpreted by considering the octahedral geometry of the Fe$^{3+}$ and Cu$^{2+}$ into monolacunary [PVMo$_{10}$O$_{39}$]$^{8-}$ ligand, and were discussed by considering noninteracting Fe$^{3+}$ and Cu$^{2+}$ ions, respectively. The powder EPR spectrum obtained in the X-band at room temperature for complex 2 (fig. 4A) contains three main feature at the effective g values at 7.942, 4.265 and 1.997 specific for Fe$^{3+}$ ions. Hyperfine structure of lines with axial symmetry, characteristic for vanadium ion addenda, was solved in $g \approx 2$ area. The EPR spectrum of compound 2 exhibits a broad signal at $g_{eff} = 4.265$, which corresponds to the high state S=5/2 of Fe$^{3+}$. Also, the g value ($g_{eff} = 7.942$), greater than 6.0 indicates that at this temperature the complex 2 is characterized by one S $\geq$ 5/2 spin state [23, 24].
Four lines with metallic hyperfine structure are included in EPR spectrum of copper complex 5 (fig. 4B), both parallel and in perpendicular bands. The powder EPR spectrum of compound 5 was discussed by considering non-interacting Cu²⁺ ions, $g_\| = 2.329$, $g_\perp = 2.124$ principal gyromagnetic values and $A_\| = 150$ G, line widths. These values indicate an axial symmetry around the Cu²⁺ ions [25]. The powder EPR spectra of the compounds 2 and 5, obtained in the X band at room temperature are typical for mononuclear species.

Figure 5 shows the XRD patterns of the α-Keggin monovanado-decamolybdophosphate investigated powders. The XRD diffraction patterns illustrates the fact that the 4, 4', and 5 investigated compounds obtained in our synthesis conditions are single phase materials containing mainly the α-Keggin monovanado-decamolybdophosphate monoclinic $P2_1/c$ structure phase [26]. Both crystallization ability with a different number of water molecules and the efflorescence phenomena are specific properties of Keggin polyoxometalates and justifies getting the same structural type for 4 and 4', which are coordination compounds of Ni²⁺ with L [1, 27]. The intense peak at 2θ = 9.4° in the XRD pattern seems to indicate that the compound may have layered type of structure [28].

The Rietveld calculation provides the crystallographic information by comparing the model profile with X-ray or neutron curves using the least squares method. One uses Rietveld analysis generally to get the lattice parameters, atomic positions and atomic distances [29]. The peak positions of X-ray diffraction patterns are related to the unit cell lattice constants of the crystal structure and peak intensities are affected by various parameters such as atomic position, atomic occupancy, and thermal effect. Rietveld method based on pseudo-Voigt profile fitting function was applied to perform a simultaneous refinement of X-ray diffraction patterns concerning both material structure and microstructure. Microstructural informations obtainable by the X-ray Rietveld refinement method consist of effective crystallite mean size, $D_{\text{eff}}$ (nm), and the root mean square (rms) of the microstrains, $<\varepsilon^2>$ [30].

The Rietveld refinement of the X-ray diffraction data has been done using the PowderCell software [31].

To simulate the X-ray powder diffraction patterns of the α-Keggin molbdophosphates monoclinic structure, the space group $P2_1/c$ (SG 14) was used as input parameters. The background of each pattern was fitted by a fourth order polynomial function. First, the background was refined; the positions of the peaks were corrected for zero-shift error by successive refinements and then the structural and microstructural parameters were refined. The unit cell parameters, the effective crystallite mean size, $D_{\text{eff}}$ (nm), the root mean square (rms) of the microstrains, $<\varepsilon^2>$, and profile (Rp) discrepancy indices at their reached minimum values calculated by Rietveld refinement analysis using PowderCel computer program for the investigated samples are presented in table 1.

The electrochemical behaviour of compounds 2 and 5, was studied by recording cyclic voltammograms in 0.25 M solution of Na₂SO₄ (pH 2.5 or 5.1) (fig. 6A and 6B). For compound 5, in the potential range of -1.5 to 1 V, voltammograms reveal the appearance of some consecutive waves placed at $E_{pc.1} = 0.34$ and $E_{pc.2} = 0.15$; $E_{pc.3} = -0.40$ and $E_{pc.4} = -0.95$ V vs. Ag/AgCl, KCl sat (at pH 2.5 and scan rate 25 mV/s) as presented in literature for similar compounds [32, 33].

The quasi-reversible (wave I) or irreversible (wave II and III) redox processes are supposed to correspond to the behaviour of Cu(II) → Cu(0) (wave 1/1'), or to the reduction of V and Mo ions from phosphovanadomolybdate structure (waves IIc and IIIc, respectively) [34, 35]. The compound 2 presents a similar behaviour with the 5 compound; the redox behaviour of iron ions being covered by the other processes (fig. 6A). At pH 5.1, the cathodic scan of compound 5 reveals only two waves placed at $E_{pc.1} = -0.40$ and $E_{pc.2} = -0.95$ V vs. Ag/AgCl, KCl sat (at pH 5.1 and scan rate 25 mV/s), probably due to a

Fig. 7 The influence of the pH (A) and of the scan rate (B) of 10^{-4} \text{M} compound 5 on graphite electrode. Inset: vs. V^0 dependence at pH 2.5 (■) and pH 5.1 (□). Experimental conditions: electrolyte, Na_2SO_4 0.25 M, pH 2.5 (thin solid line and dash dot line on A and all lines on B), pH 5.1 (dash line on A); scan rate, 10 mV s^{-1} (dash line B), 25 mV s^{-1} (all line on A, dash dot line on B), 50 mV s^{-1} (dot line on B); 100 mV s^{-1} (thick solid line on B); starting potential, -1.5 V vs. Ag/AgCl, KCl sat.

superposition of the Cu on the Mo or V behaviour (fig. 6B).

In order to identify the contribution of the Cu^{2+} ions, on the redox response of compound 5, increasing volumes of 1 mM CuSO_4 were added to 1 mM compound 5 solution, and the corresponding cyclic voltammograms were recorded in figure 6B. In the experimental done conditions, the addition of CuSO_4 leads to a significant increase of the I_{pa,1} and I_{pa,2} peaks current.

Generally, the reduction of the polyoxometalates is accompanied by protonation, therefore in figure 7A, it can be observed that as expected, the increase of the electrolyte pH value lead to a negative shift of recorded cyclic voltammograms. The influence of the scan rate on the redox behaviour of compound 5 is show in figure 7B. It is worth to underline that, the slopes of the log-log dependence between the peak currents and the potential scan rate for the peak I, of the complex 5 are equal to 0.38 ± 0.05 A/(V s^{-1}) (R = 0.9845, n = 4) and 0.85 ± 0.05 A/(V s^{-1}) (R = 0.9973, n = 4) at pH 2.5 and pH 5.1, respectively. In spite of the fact that at pH 5.1, the absorption of the compound as electrocatalyst and electron transfer is show in figure 7B.

The IR spectra show that the K[PVMo_{12}O_{40}] . 16H_2O act as pentadentate ligand with octahedral coordination involving the oxygen atoms from corner-sharing and edge-sharing octahedron of monoclinic and the oxygen atom from one water coordination molecule. Visible electronic and EPR spectra indicate O_6 local symmetry for transition metal cations in studied compounds.

The XRD patterns of K[Li(H_2O)PVMo_{12}O_{40}] . xH_2O (x = 16, 21) and K[Co(H_2O)PVMo_{12}O_{40}] . 17H_2O salts show that the complexes crystalized in monoclinic system, space group P2_1/c and change both the number of crystallization water molecules and metal cation coordinated led only to change the unit cell parameters.

while the intensity of peak I_c is unaffected by the presence of H_2O_2.

Conclusions

This work reports the synthesis and characterization of the potassium salt of the monosubstituted α-Keggin monovanado-decamolybdophosphate with Mn^{2+}, Fe^{3+}, Co^{2+}, Ni^{2+} and Cu^{2+} cations, a very interesting category of compounds, because of the catalytic and biologic properties of the vanadium element.

The complexes were synthesized in aqueous solution, by the direct addition of transition metal cations to a solution of the monolacunary Keggin polyoxo-monovanado-decamolybdophosphate anion. Elemental analysis is in good agreement with calculated values for general formula of K_8[M^{n+}(H_2O)PVMo_{12}O_{40}]. xH_2O.

The IR spectra show that the K[PVMo_{12}O_{40}] . 16H_2O act as pentadentate ligand with octahedral coordination involving the oxygen atoms from corner-sharing and edge-sharing octahedron of monoclinic cavity and the oxygen atom from one water coordination molecule.

Visible electronic and EPR spectra indicate O_6 local symmetry for transition metal cations in studied compounds.

The XRD patterns of K[Li(H_2O)PVMo_{12}O_{40}] . xH_2O (x = 16, 21) and K[Co(H_2O)PVMo_{12}O_{40}] . 17H_2O salts show that the complexes crystalized in monoclinic system, space group P2_1/c and change both the number of crystallization water molecules and metal cation coordinated led only to change the unit cell parameters.

The preliminary electrochemical behaviour of compound K[Li(H_2O)PVMo_{12}O_{40}] . 17H_2O investigated at different scan rate and different pH values exhibited successively quasi-reversible (peak I/I_c) and irreversible (peaks II_c, III_c) waves. The redox processes attributed to peak I/I_c is a mixed ones, being both diffusion- and surface-controlled and sensitive at the pH of solution. The electroreduction of H_2O_2, electrocatalysed by both Mo and V ions of compound K[Co(H_2O)PVMo_{12}O_{40}] . 17H_2O, was also evidenced and is revealing potential applications of the compound as electrocatalyst and electron transfer device.
